Brain is Exposed to Cellphone Radiation (Dr. Shalita)

Electromagnetic Hyper-Sensitivity; electro-phobia

There is no evidence of causality between pains and RF exposure

Measurement of Radiation (partly Dr. Zamir Shalita, BS.1698)

Questions to be raised

Monitoring of human exposure around the world reveals that the levels are very low, relative to ICNIRP reference levels:

- 2001 to 2004 (WHO 2007:30), UK conducted radio surveys at 289 schools with base stations on or near them. The highest levels measured anywhere were 3.5 x 10⁻³ (= 12.2 x 10⁻⁶ of the power density), with the 90% of the schools having a highest compliance factor below 2.9 x 10⁻⁴ (8.4 x 10⁻⁸ power density) which are very low values indeed.
- See also <u>IARC 2013</u>:58, fig. 1.11 specifies a cumulative distribution of exposure quotients corresponding to 3321 spot measurements made by OFCOM at 499 sites where public concern had been expressed about nearby base stations; the quotient values are median 8.1×10⁻⁶ of ICNIRP power density, ranging from the 5th percentile 3.0×10⁻⁸ to 95th percentile 2.5×10⁻⁴.
- Two hundred randomly selected people in urban, sub-urban, and rural subgroups have measured on 2005–2006 in France (Viel et al. 2009; see also <u>IARC 2013</u>:114) for 24 hours a day, 184 daily measurements. At the GSM 900/1800 bands most of the time, the recorded field strength was below detection level (**0.05 V/m**); **0.05 V/m is 3.63%** of the ICNIRP level at 900 MHz. 12.3% of measurements at the FM band indicate field strength above the detection threshold; the mean field strength was 0.17 V/m (Viel et al. 2009:552), the maximum field strength was always lower than 1.5 V/m. ANFR 2007 reveals that at 2004-2007, the average measurements are less than 2% of the field strength limit (less than 0.04% of power density); more than 75% of the measurements were less than 2% of the field strength limit, regardless of the frequency band considered.

So: Why do we need to make so many measurements? May be ICNIRP reference levels are too high?

What is the minimal Tx power (not from handset) to measure and approve RF hazards?

Reference levels: <u>ICNIRP 2010</u> compared to <u>ICNIRP 1998</u> till 10 MHz

for non-thermal effects, ICNIRP 2010 is relevant for frequencies up to 10 MHz

---- ICNIRP 1998; General Public Exposure (V/m) ---- ICNIRP 2010; General Public Exposure (V/m)

- 1. ICNIRP reconfirmed its 1998 RF guidelines in 2009 and started revision of RF guidelines in 2012
- 2. WHO & ICNIRP collaborate to publish the Environment Health Criteria (EHC) monograph by 2016
- 3. Monograph may be the basis to revise the ICNIRP (1998) and ICNIRP 2010 RF exposure guidelines
- 4. ICNIRP states at <u>http://www.icnirp.org/en/activities/work-plan/details/work-plan-hf.html</u> "The Guidelines for limiting exposure to time-varying electric, magnetic and electromagnetic fields (up to 300 GHz) published in 1998 are now being revised and replaced step by step, as explained in the <u>Statement on EMF guidelines (</u>2009). Revision of the LF and static parts are finalized. Currently, ICNIRP is revising the guidelines on limiting exposure to high and radiofrequency fields in the range 24 (**100 kHz** 300 GHz)."

Specific Absorption Rate (SAR) limits for portable wireless devices

 The SAR is determined from measurements of the Efield (e) in an anatomically-correct phantom model (liquid-filled dielectric shell) of the human head using a robotically-scanned miniature E-field probe

 The SAR (W/kg) is determined from the relationship between E and the tissue properties, i.e.,

SAR =
$$\sigma |e^2|/\rho$$

where σ is the liquid conductivity and ρ is the density

SAR is "the time derivative of the incremental energy (dW) absorbed by (dissipated in) an incremental mass (dm) contained in a volume element (dV) of a given mass density (ρ_m)" (ITU-T 2012 K.91:9) in W/kg

$$SAR = \frac{d}{dt} \left(\frac{dw}{dm} \right) = \frac{d}{dt} \left(\frac{dw}{\rho_m dv} \right)$$

SAR can be ascertained in three ways as indicated by the following equations:

- E : value of the internal electric field strength in the body tissue (V/m)
- σ : conductivity of body tissue (S/m) (siemens per meter, or mho per meter)

$$SAR = \frac{\sigma e^2}{\rho} = C_i \frac{dT}{dt} = \frac{J^2}{\sigma \rho}$$

- P : mass density of body tissue (kg/m³)
- C_i : heat capacity of body tissue (J/kg °C)
- dT/dt : time derivative of temperature in body tissue (°C/s)
- J : value of the induced current density in the body tissue (A/m^2) .

Maximal power from handsets: Specific Absorption Rate, SAR (W/kg)

$$\vec{s} = \vec{e} \times \vec{h} = \frac{eirp}{4\pi d^{2}} = \frac{\vec{e} \times \vec{e}}{120\pi} \quad |\vec{s}| = \frac{e^{2}}{z_{o}} = \frac{e^{2}}{120\pi} \quad e = \frac{\sqrt{30\,eirp}}{d}; d = \frac{\sqrt{30\,eirp}}{e}$$

where:

 μ_0 :

 $p_{\rm t}$: transmitter power (watts)

 $g_{\rm t}$: transmitter antenna gain (numeric)

eirp: equivalent isotropically radiated power (watts)

s: power density (watts/m²) (limit)

d: distance (m)

- e: electric field strength (V/m) (limit)
- z_0 : impedance of free-space, 120 π (Ohms)
 - vacuum permeability (or magnetic constant)
- ϵ_{0} : vacuum permittivity (or electric constant)
- $c_{0:}$ speed of light in vacuum

multiple-antenna emissions from the same site and same frequency

at a frequency range whose limits are frequency independent (like 10–400 MHz and 2–300 GHz), the power density limits are equal for all transmitters emitting at the same frequency range, i.e. $s_{11} = s_{12} = ... = s_1$. The equivalent cumulative *eirp* is the power scalar sum of all the emitters; this equivalent *eirp* is used to calculate the safety-distance in <u>ICNIRP 1998</u> tables 6 and 7

$$eirp_{eq} = \sum eirp_i$$
 $d_{eq} = \sqrt{\frac{eirp_{eq}}{4\pi s_l}} = \sqrt{\frac{\sum eirp_i}{4\pi s_l}}$

the total field strength exposure ration $w_{\rm t}$

$$w_t = \sum_i \left(\frac{e_i}{e_l}\right)^2 = \frac{\sum_i (e_i)^2}{(e_l)^2} \le 1$$

Where

eirp _i :	for each emitter	(watts)
<i>eirp</i> _{eq} :	equivalent cumulative <i>eirp</i>	(watts)
d _i :	safety-distance from each emitter	(m)
d_{eq} :	equivalent cumulative safety-distance	(m)
<i>s</i> _i :	power density from each emitter	(W/m²) index i
s _{li} :	power density <u>l</u> imit from each emitter	(W/m²) index i
e_{i} :	electric field strength from each emitter	(V/m) index i
e _{li} :	electric field strength <u>l</u> imit from each emitter	(V/m) index i

Emissions transmitted from the same site: multiple-antenna installation

ICNIRP 1998 limits are RF dependent; the equivalent cumulative safety-distance d_{ea}

$$d_{eq} = \sqrt{\sum_{i} d_{i}^{2}} \quad d_{i} = \sqrt{\frac{eirp_{i}}{4\pi s_{i}}}$$

• *eirp* is weighted by the inverse of its power density limit s_{li}

$$d_{eq} = \sqrt{\sum_{i} d_{i}^{2}} = \sqrt{\sum_{i} \frac{eirp_{i}}{4\pi s_{li}}} = \sqrt{\frac{eirp_{1}}{4\pi s_{l1}}} + \frac{eirp_{2}}{4\pi s_{l2}} + \dots + \frac{eirp_{n}}{4\pi s_{ln}}$$

• check the limit compliance at each frequency band relative to the threshold s_1 (or e_1); total exposure quotient (or cumulative exposure ratio) based on total cumulative weighted PD s_t

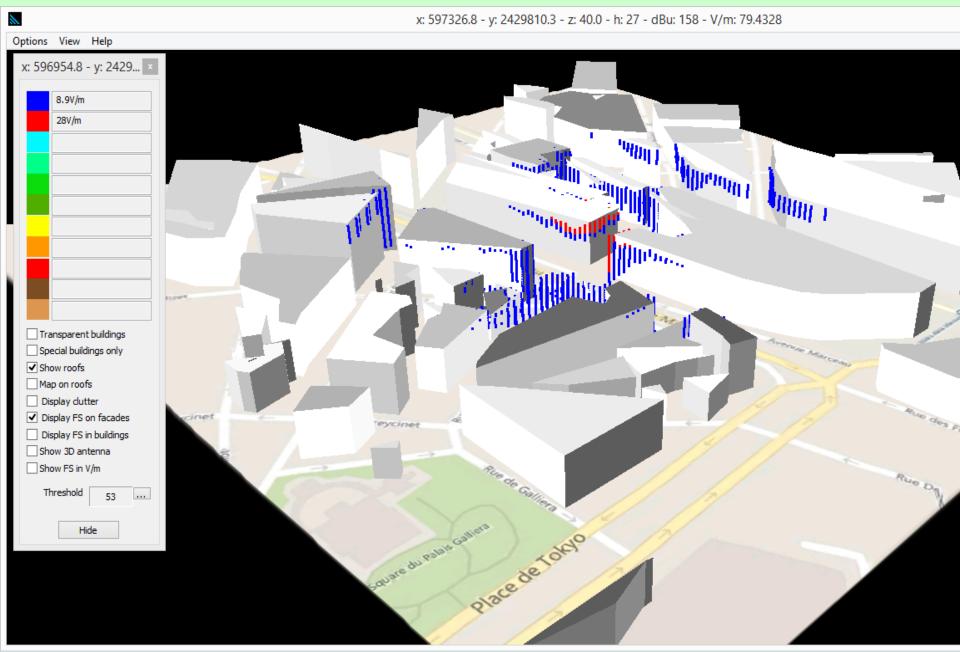

$$s_{t} = \sum_{i=1}^{n} \frac{s_{i}}{s_{li}} = \frac{s_{1}}{s_{l1}} + \frac{s_{2}}{s_{l2}} + \dots + \frac{s_{n}}{s_{\ln}} \le 1$$

total cumulative weighted field strength exposure ration w_t

See table in next slide, and <u>Coefficient Wt vs. distance for co-located site with FM</u>

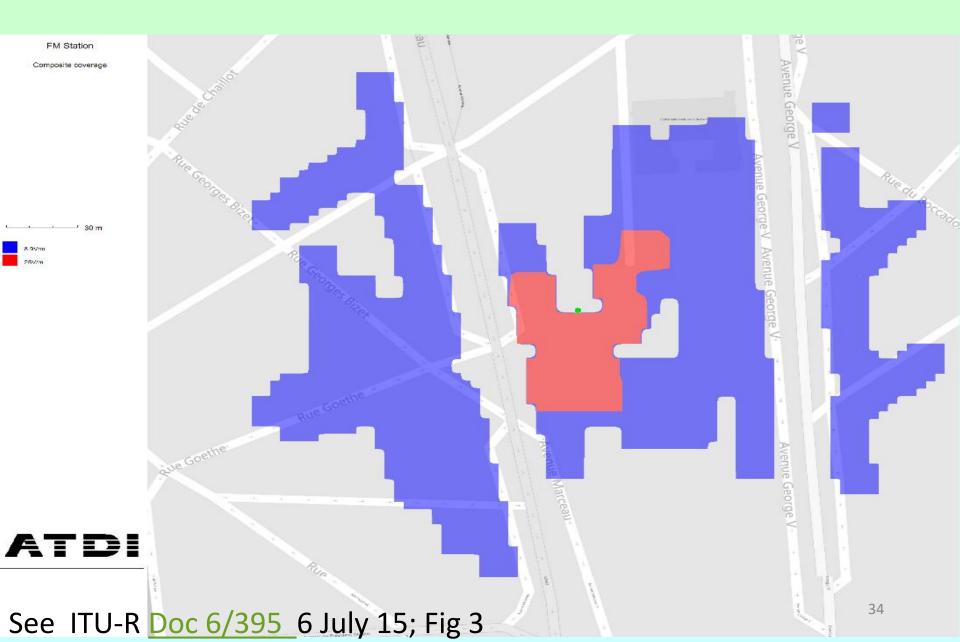

$$w_t = \sum_i \left(\frac{e_i}{e_{li}}\right)^2 \le 1$$

Three dimensions FM safety-distances: 100MHz transmitter of 60,000Watts eirp, 60m

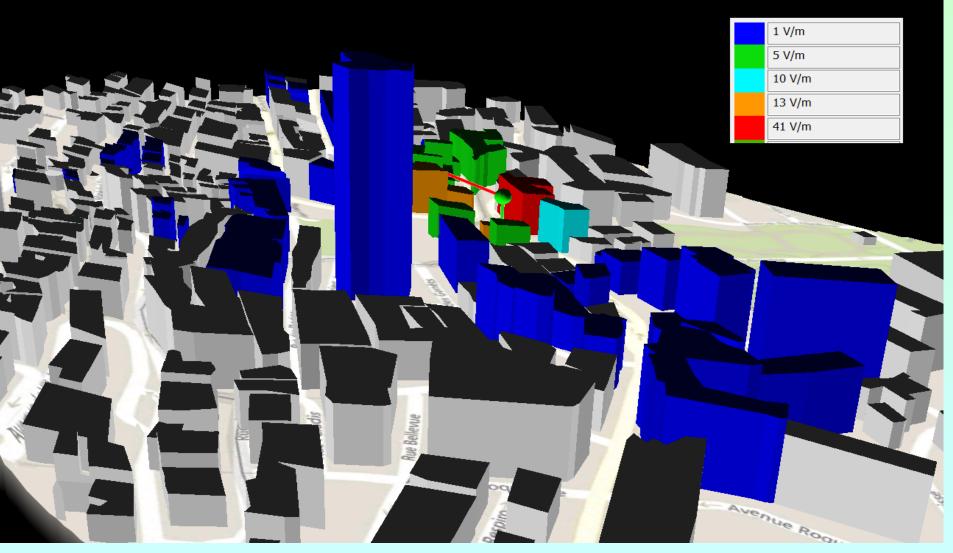

See contribution of ATDI: ITU-R Doc 6/395 6 July 15; Fig 2

RF = 1875.8 MHz; red- measured, green- calculated

Measured and calculated by ANATEL 2012, Eng . Agostinho Linhares de Souza Filho

- RF Hazards limits & their impact on network planning **Excessive limits affect network planning**
- Co-location and MIMO increase the safety distance and restrict mast construction near buildings
- Countries (e.g. Switzerland) reduce by 100 (and Salzburg by 9,000) the power density level and restrict the cellular BTS planning and location
- Lower RF exposure limits enforce to decrease the EIRP (in order to reduce the power density and field strength near the station) or to extend the distance of the mast from the public
- Handling low exposure thresholds by additional cellular antennas or RF Spectrum

Mitigation techniques to decrease the radiation level (1)

- Avoid wireless communications if the transmitter & receiver stations are fixed
 - Avoid WiFi routers based on cellular infrastructure
 - Use Satellite and Cable TV
- Maximize sharing, including active frequencies sharing among cellular operators
- Maximize the RF to operators in order to decrease sites

Mitigation techniques to decrease the radiation level (2)

- Restrict access to areas where the exposure limits are exceeded. Physical barriers, lockout procedures and adequate signs are essential; workers can use protective clothing (ITU-T 2004 <u>K.52</u> p.19)
- Increase, if possible, the antenna height. The distances to all points of investigation are increased and the radiation level is reduced. Moreover, additional attenuation to the radiation is achieved due to the increase of elevation angle and decrease of transmitting antenna sidelobe (ITU-T 2007 K.70 p.22)
- Minimize exposure to the min. needed to maintain the quality of the service, as quality criterion. Decrease the Tx power & consequently decrease linearly the power density in all the observation points. As it reduces the coverage area, it is used only if other methods cannot be applied (2007 <u>K.70</u> p.22)
- Increase the antenna gain (mainly by reducing the elevation beam width), and consequently decrease the radiation in the direction accessible to people. The vertical beam width may be used to reduce the radiation level in close proximity to the antenna. Moreover, the same value of the EIRP can be achieved by a low power transmitter feeding high gain antenna or by high power transmitter feeding low gain antenna. As far as the protection against radiation is concerned, a much better choice is to use the low power transmitter feeding the high gain antenna. (ITU-T 2007 K.70 p.22)

Low exposure thresholds by additional cellular antennas or RF Spectrum Simplistic equations; see Mazar Wiley book, to be published April 2016

For a given network (technology, number of sites, RF spectrum, quality of service), better coverage is achieved by transmitting at higher effective power (for both downlink and uplink channels), installing base stations at higher altitude above ground level (less signal attenuation) and using lower radio frequency.

Max. channel capacity for each communications link in a given network is derived from Shannon Hartley monumental paper (**Shannon 1948 p.43, theorem 17**), relating <u>capacity</u> (bit/s), RF <u>b</u>andwidth (Hz) and the <u>signal to <u>n</u>oise (dimensionless) ratio</u>

$$c = b \times \log_2\left(1 + s / n\right)$$

Moreover, in urban scenario *s/n* is small. LTE RSRQ (Reference Signal Received Quality) quantifies the capacity; UE measures this parameter as reference signal. Values higher than –9dB guarantee the best subscriber experience; the range between –9 and –12dB can be seen as neutral with a slight degradation of Quality of Service. So for *s/n* very small relative to 1, 5.1 aims to:

$$c = b \times \log_2 \left(1 + s / n\right) \approx b \times \frac{s / n}{\ln 2} \approx 1.44 \times b \times s / n$$

Therefore, staying with the same *capacity C*- less sites (reduced *S*) can be compensated by more frequency *band* (*b*).

The capacity is limited by power *s* and noise density n_o .

Summary: cellular capacity is limited by power and noise; adding RF to base stations may decrease the number of base stations and the total EMF
